A 25-year-old man presented with acute visual loss (20/400) following a Coxsackievirus prodrome approximately 1 month earlier. Multimodal imaging revealed a round, yellowish, placoid macular lesion with pinpoint hemorrhages, subretinal fluid (dots), and bacillary layer detachment (asterisk; Figure A,B). The patient was managed with clinical observation alone. After 21 days, visual acuity improved to 20/25, with resolution of the macular abnormalities (Figure C, D), consistent with the self-limiting nature of unilateral acute idiopathic maculopathy (UAIM)⁽¹⁾. Coxsackievirus infection has been implicated as a potential cause of this condition^(2,3).
